Updated this week: CoinTracker 1.0 is now live. Introduction The state of cryptocurrency volatility is a result of a multitude of things: the ever-changing landscape of altcoins, people's growing understanding of cryptocurrency and its value, the disruptive nature of new protocols and coins, and of course, the effect of exchanges in the global market. To better comprehend the state of cryptocurrency volatility, we must first understand the cause of volatility. For those unfamiliar, cryptocurrency is a very decentralized network that allows people to store value and transfer value quickly and safely. When someone sends a transaction to the blockchain, it is stored in blocks which are then connected to other blocks creating a network of blocks. Since the blockchain is decentralized and it's very common for people to have their own servers and clients, it's very common for people to have their own copy of the blockchain. This can lead to a variety of issues where data is stored on various servers and not all servers have access to the entire blockchain. These issues are known as hard forks. Hard forks are not always bad. For example, a hard fork of Bitcoin Cash occurred in 2017 as a result of a hard fork of Bitcoin. This fork was a result of a desire to increase the blocksize limit. Since the original Bitcoin protocol limits the size of blocks, Bitcoin Cash will have a larger limit. The increased block size allowed more people to use the currency. Additionally, increased security was also a benefit of this fork. However, as more and more people began using Bitcoin Cash, the value of Bitcoin Cash grew. Since the value of Bitcoin Cash had grown, Bitcoin saw its value drop. Bitcoin saw a 9.3% drop in value in the 24 hour period after the fork was triggered. The chart below is a visual representation of the price changes of Bitcoin Cash. Hard forks can also be beneficial. For example, the Bitcoin Segwit hard fork was also a hard fork that was used to implement SegWit. The SegWit protocol was 82157476af
